

Integrator Series FPGAs: 1200XL and 3200DX Families

Features

High Capacity

- 2,500 to 40,000 Logic Gates
- Up to 4 Kbits Configurable Dual-Port SRAM
- Fast Wide-Decode Circuitry
- Up to 288 User-Programmable I/O Pins

High Performance

- 225 MHz Performance
- 5 ns Dual-Port SRAM Access
- 100 MHz FIFOs
- 7.5 ns 35-Bit Address Decode

Ease-of-Integration

- Synthesis-Friendly Architecture Supports ASIC Design Methodologies.
- 95–100% Device Utilization using Automatic Place and Route Tools.
- Deterministic, User-Controllable Timing Via DirectTime Software Tools with Up To 100% Pin Fixing.
- Supported by Actel Designer Series Development System with Interfaces to Popular Design Environments including

Cadence, Escalade, Exemplar, IST, Mentor Graphics, Synopsys, and Viewlogic.

- IEEE Standard 1149.1 (JTAG) Boundary Scan Testing.

General Description

Actel's Integrator Series FPGAs are the first programmable logic devices optimized for high-speed system logic integration. Based on Actel's proprietary antifuse technology and 0.6-micron double metal CMOS process, Integrator Series devices offer a fine-grained, register-rich architecture with the industry's fastest embedded dual-port SRAM and wide-decode circuitry.

Integrator Series' 3200DX and 1200XL families were designed to integrate system logic which is typically implemented in multiple CPLDs, PALs, and FPGAs. These devices provide the features and performance required for today's complex, high-speed digital logic systems. The 3200DX family offers the industry's fastest dual-port SRAM for implementing fast FIFOs, LIFOs, and temporary data storage. The large number of storage elements can efficiently address applications requiring wide datapath manipulation and transformation functions such as telecommunications, networking, and DSP.

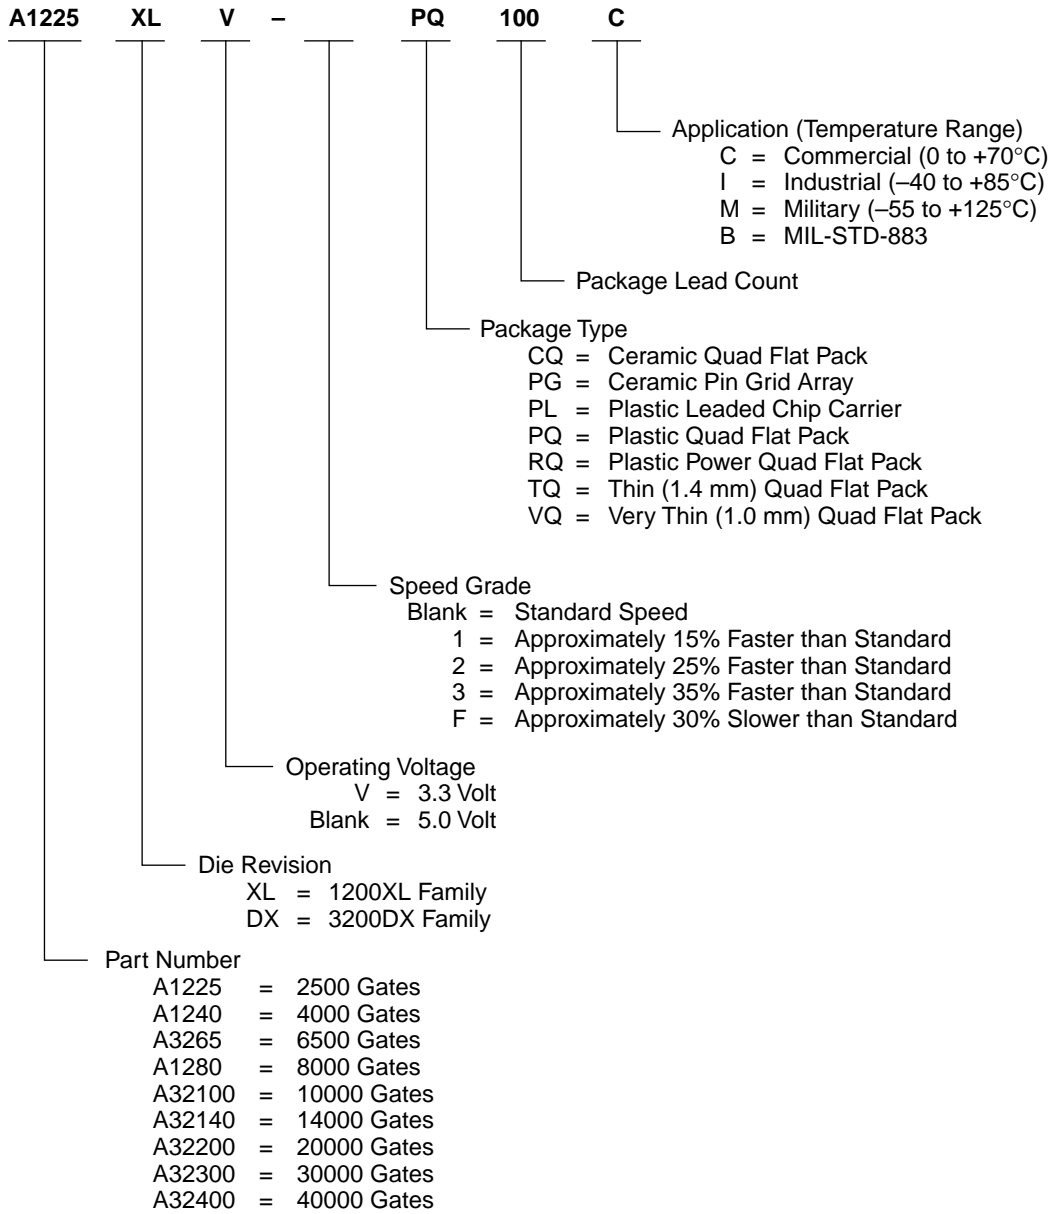

Integrator Series Product Profile

Note 1: Logic gate capacity does not include SRAM bits as logic.

Ordering Information

Integrator Series devices are supported by Actel's Designer Series development software, which provides a seamless integration into many ASIC design flows. The Designer Series development tools offer automatic place and route (even with pre-assigned pins), static timing analysis, user programming, and debug and diagnostic probe capabilities. The Designer Series DirectTime tool provides deterministic and controllable timing, allowing the designer to specify the performance requirements of individual paths and system clock(s). Using these specifications, the software will automatically optimize the placement and routing of the logic to meet these constraints. Also included with the Designer Series tools is Actel's ACTGen Macro Builder, which allows designers to quickly build fast, efficient logic functions such as counters, adders, FIFOs, and RAM.

The Designer Series tools provide designers the capability to move up to high-level description languages, such as VHDL

and Verilog-HDL, or use schematic design entry with interfaces to most EDA tools. Designer Series is supported on the following development platforms: 486 and Pentium PC, Sun and HP workstations. The software provides CAE interfaces to Cadence, Mentor Graphics, Escalade, OrCAD and Viewlogic design environments. Additional development tools are supported through Actel's Industry Alliance Program, including Data I/O (ABEL FPGA) and MINC.

Actel's FPGAs are an efficient solution for shortening the system design and development cycle, and they offer a cost-effective alternative for low to medium volume production runs. The 3200DX and 1200XL devices are an excellent choice for integrating logic that is currently implemented in multiple PALs, CPLDs, and FPGAs. Some example applications include high-speed controllers and address decoding, peripheral bus interfaces, DSP, and co-processor functions.

Pin Description

CLKA, CLKB Clock A and Clock B (Input)

TTL clock inputs for clock distribution networks. The clock input is buffered prior to clocking the logic modules. This pin can also be used as an I/O.

DCLK Diagnostic Clock (Input)

TTL clock input for diagnostic probe and device programming. DCLK is active when the MODE pin is HIGH. This pin functions as an I/O when the MODE pin is LOW.

GND Ground (Input)

Input LOW supply voltage.

I/O Input/Output (Input, Output)

I/O pin functions as an input, output, three-state or bi-directional buffer. Input and output levels are compatible with standard TTL and CMOS specifications. Unused I/O pins are automatically driven LOW by the Designer Series software.

MODE Mode (Input)

The MODE pin controls the use of multi-function pins (DCLK, PRA, PRB, SDI, TDO). When the MODE pin is HIGH, the special functions are active. To provide ActionProbe capability, the MODE pin should be terminated to GND through a 10K resistor so the MODE pin can be pulled HIGH when required.

NC No Connection

This pin is not connected to circuitry within the device.

PRA/I/O Probe A (Output)

The Probe A pin is used to output data from any user-defined design node within the device. This independent diagnostic pin is used in conjunction with the Probe B pin to allow real-time diagnostic output of any signal path within the device. The Probe A pin can be used as a user-defined I/O when debugging has been completed. The pin's probe capabilities can be permanently disabled to protect programmed design confidentiality. PRA is active when the MODE pin is HIGH. This pin functions as an I/O when the MODE pin is LOW.

PRB/I/O Probe B (Output)

The Probe B pin is used to output data from any user-defined design node within the device. This independent diagnostic pin is used in conjunction with the Probe A pin to allow real-time diagnostic output of any signal path within the device. The Probe B pin can be used as a user-defined I/O when debugging has been completed. The pin's probe capabilities can be permanently disabled to protect

programmed design confidentiality. PRB is active when the MODE pin is HIGH. This pin functions as an I/O when the MODE pin is LOW.

QCLKA/B,C,D Quadrant Clock (Input/Output)

These four pins are the quadrant clock inputs. When not used as a register control signal, these pins can function as general purpose I/O.

SDI Serial Data Input (Input)

Serial data input for diagnostic probe and device programming. SDI is active when the MODE pin is HIGH. This pin functions as an I/O when the MODE pin is LOW.

TCK Test Clock

Clock signal to shift the JTAG data into the device. This pin functions as an I/O when the JTAG fuse is not programmed.

TDI Test Data In

Serial data input for JTAG instructions and data. Data is shifted in on the rising edge of TCLK. This pin functions as an I/O when the JTAG fuse is not programmed.

TDO Test Data Out

Serial data output for JTAG instructions and test data. This pin functions as an I/O when the JTAG fuse is not programmed.

TMS Test Mode Select

Serial data input for JTAG test mode. Data is shifted in on the rising edge of TCLK. This pin functions as an I/O when the JTAG fuse is not programmed.

V_{CC} Supply Voltage (Input)

Input HIGH supply voltage.

Note: *TCK, TDI, TDO, TMS are only available on devices containing JTAG circuitry.*

Integrator Series Architectural Overview

The 1200XL and 3200DX architecture is composed of fine-grained building blocks which produce fast, efficient logic designs. All devices within the Integrator Series are composed of logic modules, routing resources, clock networks, and I/O modules which are the building blocks to design fast logic designs. In addition, a subset of devices contain embedded dual-port SRAM and wide-decode modules. The dual-port SRAM modules are optimized for high-speed datapath functions such as FIFOs, LIFOs, and scratchpad memory. "Integrator Series Product Profile" on page 1 lists the specific logic resources contained within each device.

Logic Modules

3200DX and 1200XL devices contain three types of logic modules: combinational (C-modules), sequential (S-modules), and decode (D-modules). 1200XL devices contain only the C-module and S-module, while the 3200DX devices contain D-modules and dual-port SRAM modules in addition to the S-module and C-module.

The C-module is shown in Figure 1 and implements the following function:

$$Y = !S1 * !S0 * D00 + !S1 * S0 * D01 + S1 * !S0 * D10 + S1 * S0 * D11$$

where:

$$S0 = A0 * B0$$

$$S1 = A1 + B1$$

The S-module shown in Figure 2 is designed to implement high-speed sequential functions within a single logic module. The S-module implements the same combinational logic function as the C-module while adding a sequential element. The sequential element can be configured as either a D-type

Figure 1 • C-Module Implementation

flip-flop or a transparent latch. To increase flexibility, the S-module register can be bypassed so that it implements purely combinational logic.

Figure 2 • S-Module Implementation

3200DX devices contain a third type of logic module, D-modules, which are arranged around the periphery of device. D-modules contain wide-decode circuitry which provides a fast, wide-input AND function similar to that found in product term architectures (Figure 3). The D-module allows 3200DX devices to perform wide-decode functions at speeds comparable CPLDs and PAL devices. The output of the D-module has a programmable inverter for active HIGH or LOW assertion. D-module output is hard-wired to an output pin or can be fed back into the array to be incorporated into other logic.

Dual-Port SRAM Modules

Several 3200DX devices contain dual-port SRAM modules that have been optimized for synchronous or asynchronous applications. The SRAM modules are arranged in 256 bit blocks which can be configured as 32x8 or 64x4 (refer to "Integrator Series Product Profile" on page 1 for the number of SRAM blocks within a particular device). SRAM modules

Figure 3 • D-Module Implementation

can be cascaded together to form memory spaces of user-definable width and depth. A block diagram of the 3200DX dual-port SRAM block is shown in Figure 4.

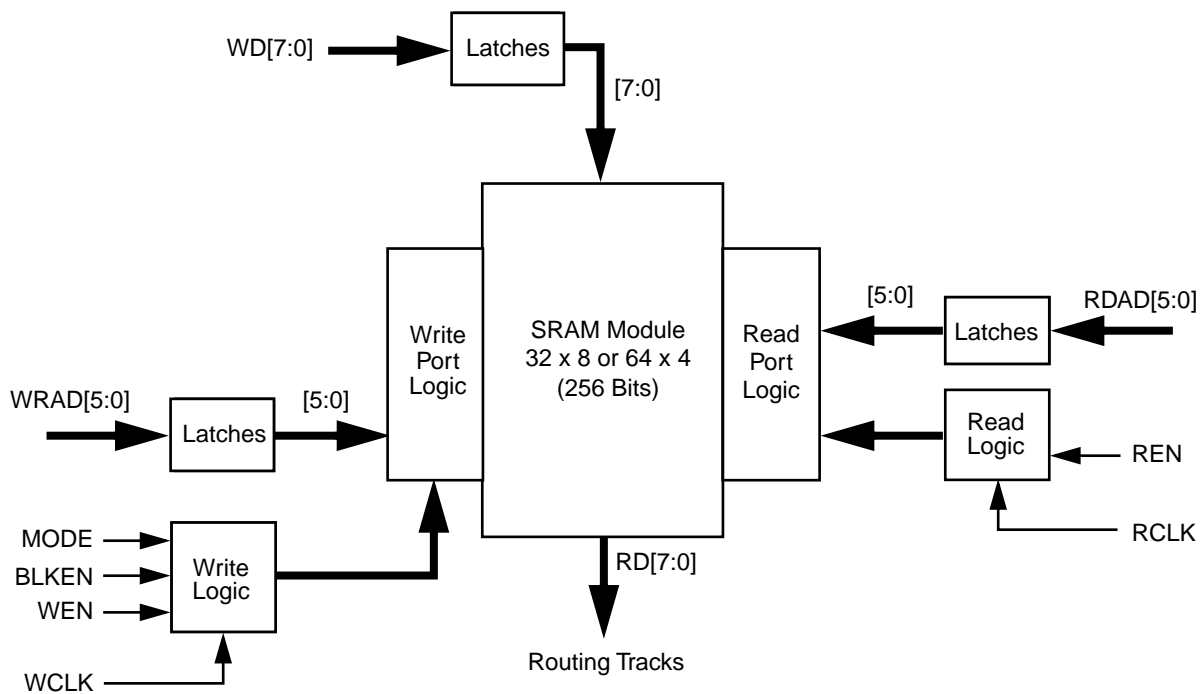

Figure 4 • 3200DX Dual-Port SRAM Block

The 3200DX SRAM modules are true dual-port structures containing independent READ and WRITE ports. Each SRAM module contains six bits of read and write addressing (RDAD[5:0] and WRAD[5:0], respectively) for 64x4 bit blocks. When configured in byte mode, the highest order address bits (RDAD5 and WRAD5) are not used. The read and write ports of the SRAM block contain independent clocks (RCLK and WCLK) with programmable polarities offering active HIGH or

LOW implementation. The SRAM block contains eight data inputs (WD[7:0]) and eight outputs (RD[7:0]) which are connected to segmented vertical routing tracks.

The 3200DX dual-port SRAM blocks provide an optimal solution for high-speed buffered applications requiring fast FIFO and LIFO queues. Actel's ACTGen Macro Builder provides the capability to quickly design memory functions,

such as FIFOs, LIFOs, and RAM arrays. Additionally, unused SRAM blocks can be used to implement registers for other logic within the design.

I/O Modules

The I/O modules provide the interface between the device pins and the logic array. Figure 5 is a block diagram of the I/O module. A variety of user functions, determined by a library macro selection, can be implemented in the module (refer to the Macro Library Guide for more information). I/O modules contain a tri-state buffer, input and output latches which can be configured for input, output, or bi-directional pins (Figure 5).

* Can be Configured as a Latch or D Flip-Flop
(Using C-Module)

Figure 5 • I/O Module

The Integrator Series devices contain flexible I/O structures where each output pin has a dedicated output enable control. The I/O module can be used to latch input and/or output data, providing a fast set-up time. In addition, the Actel Designer Series software tools can build a D-type flip-flop using a C-module to register input and/or output signals.

Actel's Designer Series development tools provide a design library of I/O macrofunctions which can implement all I/O configurations supported by the Integrator Series FPGAs.

Routing Structure

The Integrator Series architecture uses vertical and horizontal routing tracks to interconnect the various logic and I/O modules. These routing tracks are metal interconnects that may either be of continuous length or broken into pieces called segments. Varying segment lengths allows interconnection of over 90% of design tracks to occur with only two antifuse connections. Segments can be joined

together at the ends using antifuses to increase their lengths up to the full length of the track. All interconnects can be accomplished with a maximum of four antifuses.

Horizontal Routing

Horizontal channels are located between the rows of modules and are composed of several routing tracks. The horizontal routing tracks within the channel are divided into one or more segments. The minimum horizontal segment length is the width of a module pair, and the maximum horizontal segment length is the full length of the channel. Any segment that spans more than one-third the row length is considered a long horizontal segment. A typical channel is shown in Figure 6. Non-dedicated horizontal routing tracks are used to route signal nets; dedicated routing tracks are used for the global clock networks and for power and ground tie-off tracks.

Vertical Routing

Another set of routing tracks run vertically through the module. Vertical tracks are of three types: input, output, and long, and are divided into one or more segments. Each segment in an input track is dedicated to the input of a particular module; each segment in an output track is dedicated to the output of a particular module. Long segments are uncommitted and can be assigned during routing. Each output segment spans four channels (two above and two below), except near the top and bottom of the array where edge effects occur. LVTs contain either one or two segments. An example of vertical routing tracks and segments is shown in Figure 6.

Figure 6 • Routing Structure

Antifuse Structures

An antifuse is a “normally open” structure as opposed to the normally closed fuse structure used in PROMs or PALs. The use of antifuses to implement a programmable logic device results in highly-testable structures as well as efficient programming algorithms. The structure is highly testable

because there are no pre-existing connections; therefore, temporary connections can be made using pass transistors. These temporary connections can isolate individual antifuses to be programmed and individual circuit structures to be tested, which can be done before and after programming. For example, all metal tracks can be tested for continuity and shorts between adjacent tracks, and the functionality of all logic modules can be verified.

Clock Networks

Two low-skew, high-fanout clock distribution networks are provided in each 3200DX device. These networks are referred to as CLK0 and CLK1. Each network has a clock module (CLKMOD) that selects the source of the clock signal and may be driven as follows:

1. Externally from the CLKA pad
2. Externally from the CLKB pad
3. Internally from the CLKINA input
4. Internally from the CLKINB input

The clock modules are located in the top row of I/O modules. Clock drivers and a dedicated horizontal clock track are located in each horizontal routing channel.

The user controls the clock module by selecting one of two clock macros from the macro library. The macro CLKBUF is used to connect one of the two external clock pins to a clock network, and the macro CLKINT is used to connect an internally-generated clock signal to a clock network. Since both clock networks are identical, the user does not care whether CLK0 or CLK1 is being used. The clock input pads may also be used as normal I/Os, bypassing the clock networks (see Figure 7).

The 3200DX devices which contain SRAM modules (all except A3265DX and A32140DX) have four additional register control resources, called quadrant clock networks (Figure 8). Each quadrant clock provides a local, high-fanout resource to the contiguous logic modules within its quadrant of the device. Quadrant clock signals can originate from specific I/O pins or from the internal array and can be used as a secondary register clock, register clear, or output enable.

Test Circuitry

Both 3200DX and 1200XL devices provide the means to test and debug a design once it is programmed into a device. 3200DX and 1200XL devices contain Actel's ActionProbe test circuitry. Once a device has been programmed, the ActionProbe circuitry allows the designer using Silicon Explorer software to probe any internal node during device operation to aid in debugging a design. In addition, 3200DX devices contain IEEE Standard 1149.1 (JTAG) Boundary Scan Test.

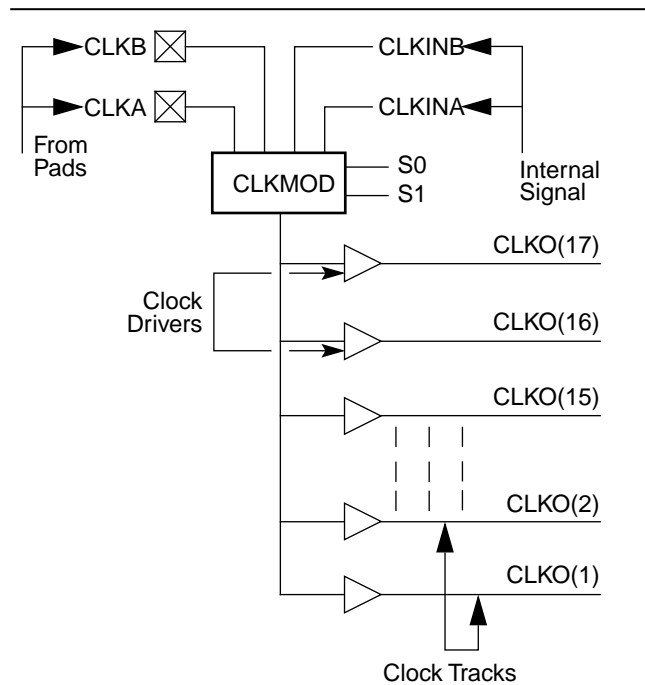

Figure 7 • Clock Networks

JTAG Boundary Scan Testing (BST)

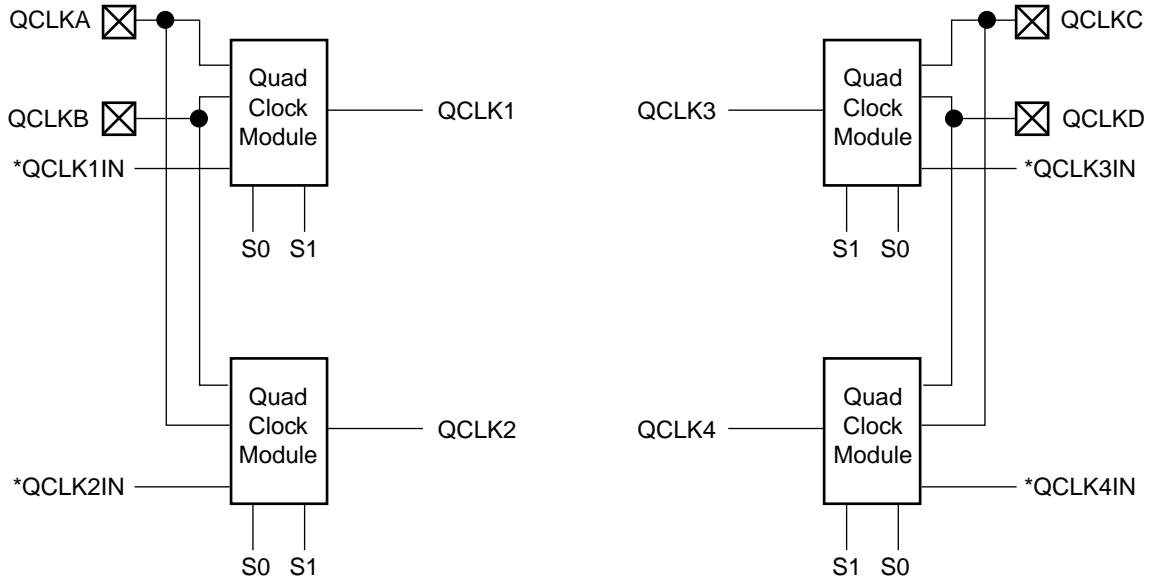

Device pin spacing is decreasing with the advent of fine-pitch packages such as TQFP and BGA packages, and manufacturers are routinely implementing surface-mount technology with multi-layer PC boards. Boundary scan is becoming an attractive tool to help systems manufacturers test their PC boards. The Joint Test Action Group (JTAG) developed the IEEE Standard 1149.1 (JTAG) Boundary Scan Test to facilitate board-level testing during manufacturing.

IEEE Standard 1149.1 defines a 4-pin Test Access Port (TAP) interface for testing integrated circuits in a system. The 3200DX family provides four JTAG BST pins: Test Data In (TDI), Test Data Out (TDO), Test Clock (TCLK) and Test Mode Select (TMS). Devices are configured in a JTAG "chain" where BST data can be transmitted serially between devices via TDO to TDI interconnections. The TMS and TCLK signals are shared between all devices in the JTAG chain, allowing all components to operate in the same state.

The 3200DX family implements a subset of the IEEE Standard 1149.1 Boundary Scan Test (BST) instruction in addition to a private instruction, which allows access to Actel's ActionProbe circuitry with JTAG BST. Refer to the IEEE Standard 1149.1 specification for detailed information regarding JTAG testing.

JTAG Architecture

The 3200DX JTAG BST circuitry consist of a Test Access Port (TAP) controller, JTAG instruction register, JPROBE register, bypass register and boundary scan register. Figure 9 is a block diagram of the 3200DX JTAG circuitry.

**QCLK1IN, QCLK2IN, QCLK3IN, and QCLK4IN are internally-generated signals.*

Figure 8 • Quadrant Clock Network

Figure 9 • JTAG BST Circuitry

When a device is operating in JTAG BST mode, four I/O pins are used for the TDI, TDO, TMS, and TCLK signals. An active reset (nTRST) pin is not supported; however, the 3200DX contains power-on circuitry which resets the JTAG BST circuitry upon power-up. During normal device operation, the JTAG pins should be held LOW to disable the JTAG circuitry. The following table summarizes the functions of the JTAG BST signals.

JTAG Signal	Name	Function
TDI	Test Data In	Serial data input for JTAG instructions and data. Data is shifted in on the rising edge of TCLK.
TDO	Test Data Out	Serial data output for JTAG instructions and test data.
TMS	Test Mode Select	Serial data input for JTAG test mode. Data is shifted in on the rising edge of TCLK.
TCLK	Test Clock	Clock signal to shift the JTAG data into the device.

JTAG BST Instructions

JTAG BST testing within the 3200DX devices is controlled by a Test Access Port (TAP) state machine. The TAP controller drives the three-bit instruction register, a bypass register, and the boundary scan data registers within the device. The TAP controller uses the TMS signal to control the JTAG testing of the device. The JTAG test mode is determined by the bitstream entered on the TMS pin. The table in the next column describes the JTAG instructions supported by the 3200DX.

ActionProbe

If a device has been successfully programmed and the security fuse has not been programmed, any internal logic or I/O module output can be observed in real time using the ActionProbe circuitry, the PRA and/or PRB pins, and Actel's Silicon Explorer diagnostic and debug tool kit. Refer to "Using the ActionProbe for System-Level Debug" application note for further information.

Test Mode	Code	Description
EXTEST	000	Allows the external circuitry and board-level interconnections to be tested by forcing a test pattern at the output pins and capturing test results at the input pins.
SAMPLE/ PRELOAD	001	Allows a snapshot of the signals at the device pins to be captured and examined during device operation.
INTEST	010	Refer to IEEE Standard 1149.1 Specification
JPROBE	011	A private instruction allowing the user to connect Actel's Micro Probe registers to the JTAG chain.
USER INSTRUCTION	100	Allows the user to build application-specific instructions such as RAM READ and RAM WRITE.
HIGH Z	101	Refer to IEEE Standard 1149.1 Specification
CLAMP	110	Refer to IEEE Standard 1149.1 Specification
BYPASS	111	Enables the by bypass register between the TDI and TDO pins. The test data passes through the selected device to adjacent devices in the JTAG chain.

5.0V Operating Conditions

Absolute Maximum Ratings¹

Free Air Temperature Range

Symbol	Parameter	Limits	Units
V_{CC}	DC Supply Voltage	-0.5 to +7.0	V
V_I	Input Voltage	-0.5 to $V_{CC} + 0.5$	V
V_O	Output Voltage	-0.5 to $V_{CC} + 0.5$	V
I_{IO}	I/O Source/Sink Current ²	± 20	mA
T_{STG}	Storage Temperature	-65 to +150	°C

Notes:

1. Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. Exposure to absolute maximum rated conditions for extended periods may affect device reliability. Device should not be operated outside the Recommended Operating Conditions.
2. Device inputs are normally high impedance and draw extremely low current. However, when input voltage is greater than $V_{CC} + 0.5V$ or less than $GND - 0.5V$, the internal protection diode will be forward biased and can draw excessive current.

Recommended Operating Conditions

Parameter	Commercial	Industrial	Military	Units
Temperature Range ¹	0 to +70	-40 to +85	-55 to +125	°C
Power Supply Tolerance	± 5	± 10	± 10	% V_{CC}

Note:

1. Ambient temperature (T_A) is used for commercial and industrial; case temperature (T_C) is used for military.

Electrical Specifications

Symbol	Parameter	Commercial		Commercial -F		Industrial		Military		Units

Standby Current, I _{CC} ⁴ (typical = 0.3 mA)		0.75	mA
I _{CC(D)} Dynamic V _{CC} Supply Current	See “Power Dissipation” on page 1-21		

Notes:

1. Only one output tested at a time. V_{CC} = min.
2. Not tested, for information only.
3. Includes worst-case 84-pin PLCC package capacitance. V_{OUT} = 0 V, f = 1 MHz.
4. Typical standby current = 0.3 mA. All outputs unloaded. All inputs = V_{CC} or GND.

Package Thermal Characteristics

The device junction to case thermal characteristic is θ_{jc} , and the junction to ambient air characteristic is θ_{ja} . The thermal characteristics for θ_{ja} are shown with two different air flow rates.

Maximum junction temperature is 150°C.

A sample calculation of the absolute maximum power dissipation allowed for a PQFP 160-pin package at commercial temperature is as follows:

$$\frac{\text{Max. junction temp. (°C)} - \text{Max. commercial temp.}}{\theta_{ja} \text{ (°C/W)}} = \frac{150^\circ\text{C} - 70^\circ\text{C}}{30^\circ\text{C/W}} = 2.6\text{W}$$

Package Type	Pin Count	θ_{ja}		Maximum Power Dissipation	
		Still Air	300 ft/min	Still Air	300 ft/min
Plastic Quad Flat Pack	100	42°C/W	33°C/W	1.9 W	2.4 W
Plastic Quad Flat Pack	144	36°C/W	29°C/W	2.2 W	2.8 W
Plastic Quad Flat Pack	160	34°C/W	27°C/W	2.4 W	3.0 W
Plastic Quad Flat Pack	208	25°C/W	16.2°C/W	3.2 W	4.9 W
Plastic Leaded Chip Carrier	84	37°C/W	28°C/W	2.2 W	2.9 W
Thin Quad Flat Pack	176	32°C/W	25°C/W	2.5 W	3.2 W
Power Quad Flat Pack	208	16.8°C/W	11.4°C/W	4.8 W	7.0 W
Power Quad Flat Pack	240	16.1°C/W	10.6°C/W	5.0 W	7.5 W
Very Thin Quad Flat Pack	100	43°C/W	35°C/W	1.9 W	2.3 W

Power Dissipation

General Power Equation

$$P = [I_{CC\text{standby}} + I_{CC\text{active}}] * V_{CC} + I_{OL} * V_{OL} * N + I_{OH} * (V_{CC} - V_{OH}) * M$$

where:

$I_{CC\text{standby}}$ is the current flowing when no inputs or outputs are changing.

$I_{CC\text{active}}$ is the current flowing due to CMOS switching.

I_{OL} , I_{OH} are TTL sink/source currents.

V_{OL} , V_{OH} are TTL level output voltages.

N equals the number of outputs driving TTL loads to V_{OL} .

M equals the number of outputs driving TTL loads to V_{OH} .

An accurate determination of N and M is problematic because their values depend on the family type, design details, and on the system I/O. The power can be divided into two components: static and active.

Static Power Component

Actel FPGAs have small static power components that result in lower power dissipation than PALs or PLDs. By integrating multiple PALs/PLDs into one FPGA, an even greater reduction in board-level power dissipation can be achieved.

The power due to standby current is typically a small component of the overall power. Standby power is calculated below for commercial worst case conditions.

I_{CC}	V_{CC}	Power
2 mA	5.25 V	10.5 mW

The static power dissipation by TTL loads depends on the number of outputs driving HIGH or LOW and the DC load current. Again, this number is typically small. For instance, a 32-bit bus sinking 4 mA at 0.33V will generate 42 mW with all outputs driving LOW and 140 mW with all outputs driving HIGH. The actual dissipation will average somewhere in between as I/Os switch states with time.

Active Power Component

Power dissipation in CMOS devices is usually dominated by the active (dynamic) power dissipation. This component is frequency-dependent, a function of the logic and the external I/O. Active power dissipation results from charging internal chip capacitances of the interconnect, unprogrammed antifuses, module inputs, and module outputs, plus external capacitance due to PC board traces and load device inputs. An additional component of the active power dissipation is the totem pole current in the CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent active power dissipation.

Equivalent Capacitance

The power dissipated by a CMOS circuit can be expressed by Equation 1

$$\text{Power } (\mu\text{W}) = C_{\text{EQ}} * V_{\text{CC}}^2 * F \quad (1)$$

where:

C_{EQ} is the equivalent capacitance expressed in picofarads (pF).

V_{CC} is power supply in volts (V).

F is the switching frequency in megahertz (MHz).

Equivalent capacitance is calculated by measuring I_{CCactive} at a specified frequency and voltage for each circuit component of interest. Measurements have been made over a range of frequencies at a fixed value of V_{CC} . Equivalent capacitance is frequency-independent, so the results may be used over a wide range of operating conditions. Equivalent capacitance values are shown below.

C_{EQ} Values for Actel FPGAs

Modules (C_{EQM})	5.2
Input Buffers (C_{EQI})	11.6
Output Buffers (C_{EQO})	23.8
Routed Array Clock Buffer Loads (C_{EQCR})	3.5

To calculate the active power dissipated from the complete design, the switching frequency of each part of the logic must be known. Equation 2 shows a piece-wise linear summation over all components.

$$\begin{aligned} \text{Power} = & V_{\text{CC}}^2 * [(m * C_{\text{EQM}} * f_m)_{\text{Modules}} + \\ & (n * C_{\text{EQI}} * f_n)_{\text{Inputs}} + (p * (C_{\text{EQO}} + C_L) * f_p)_{\text{Outputs}} + \\ & 0.5 * (q_1 * C_{\text{EQCR}} * f_{q1})_{\text{routed_Clk1}} + (r_1 * f_{q1})_{\text{routed_Clk1}} + \\ & 0.5 * (q_2 * C_{\text{EQCR}} * f_{q2})_{\text{routed_Clk2}} + (r_2 * f_{q2})_{\text{routed_Clk2}} \quad (2) \end{aligned}$$

where:

m	= Number of logic modules switching at frequency f_m
n	= Number of input buffers switching at frequency f_n
p	= Number of output buffers switching at frequency f_p
q_1	= Number of clock loads on the first routed array clock
q_2	= Number of clock loads on the second routed array clock
r_1	= Fixed capacitance due to first routed array clock
r_2	= Fixed capacitance due to second routed array clock
C_{EQM}	= Equivalent capacitance of logic modules in pF
C_{EQI}	= Equivalent capacitance of input buffers in pF
C_{EQO}	= Equivalent capacitance of output buffers in pF
C_{EQCR}	= Equivalent capacitance of routed array clock in pF
C_L	= Output load capacitance in pF

f_m	= Average logic module switching rate in MHz
f_n	= Average input buffer switching rate in MHz
f_p	= Average output buffer switching rate in MHz
f_{q1}	= Average first routed array clock rate in MHz
f_{q2}	= Average second routed array clock rate in MHz

Fixed Capacitance Values for Actel FPGAs (pF)

Device Type	r_1 routed_Clk1	r_2 routed_Clk2
A1225XL	106	106
A1240XL	134	134
A3265DX	158	158
A1280XL	168	168
A32100DX	178	178
A32140DX	190	190
A32200DX	230	230
A32300DX	285	285

Determining Average Switching Frequency

To determine the switching frequency for a design, you must have a detailed understanding of the data input values to the circuit. The following guidelines represent worst-case scenarios; they can be generally used to predict the upper limits of power dissipation.

Logic Modules (m)	= 80% of Combinatorial Modules
Inputs Switching (n)	= # of Inputs/4
Outputs Switching (p)	= # Outputs/4
First Routed Array Clock Loads (q_1)	= 40% of Sequential Modules
Second Routed Array Clock Loads (q_2)	= 40% of Sequential Modules
Load Capacitance (C_L)	= 35 pF
Average Logic Module Switching Rate (f_m)	= F/10
Average Input Switching Rate (f_n)	= F/5
Average Output Switching Rate (f_p)	= F/10
Average First Routed Array Clock Rate (f_{q1})	= F
Average Second Routed Array Clock Rate (f_{q2})	= F/2

Predictable Performance: Tight Delay Distributions

Propagation delay between logic modules depends on the resistive and capacitive loading of the routing tracks, the interconnect elements, and the module inputs being driven. Propagation delay increases as the length of routing tracks, the number of interconnect elements, or the number of inputs increase.

From a design perspective, the propagation delay can be statistically correlated or modeled by the fanout (number of loads) driven by a module. Higher fanout usually requires some paths to have longer routing tracks.

The Integrator Series delivers a very tight fanout delay distribution. This tight distribution is achieved in two ways: by decreasing the delay of the interconnect elements and by decreasing the number of interconnect elements per path.

Actel's patented PLICE antifuse offers a very low resistive/capacitive interconnect. The antifuses, fabricated in 0.6 micron lithography, offer nominal levels of 100 ohms resistance and 7.0 femtofarad (fF) capacitance per antifuse.

The Integrator Series fanout distribution is also tight due to the low number of antifuses required for each interconnect path. The proprietary architecture limits the number of antifuses per path to a maximum of four, with 90% of interconnects using two antifuses.

Timing Characteristics

Timing characteristics for devices fall into three categories: family-dependent, device-dependent, and design-dependent. The input and output buffer characteristics are common to all Integrator Series members. Internal routing delays are device-dependent. Design dependency means actual delays

are not determined until after placement and routing of the user's design is complete. Delay values may then be determined by using the Designer Series utility or performing simulation with post-layout delays.

Critical Nets and Typical Nets

Propagation delays in this data sheet apply to typical nets, which are used for initial design performance evaluation. The abundant routing resources in the Integrator Series architecture allows for deterministic timing. Using DirectTime, a timing-driven place and route tool in Actel's Designer Series development software, the designer may specify timing-critical nets and system clock frequency. Using these timing specifications, the place and route software optimize the design layout to meet the user's specifications.

Long Tracks

Some nets in the design use long tracks which are special routing resources that span multiple rows, columns, or modules. Long tracks employ three and sometimes four antifuse connections. This increases capacitance and resistance, resulting in longer net delays for macros connected to long tracks. Typically, up to 6% of nets in a fully utilized device require long tracks. Long tracks contribute approximately 3 ns to 6 ns delay, which is represented statistically in higher fanout (FO=8) routing delays in the data sheet specifications section.

Timing Derating

A timing derating factor of 0.45 is used to reflect best-case processing. Note that this factor is relative to the "standard speed" timing parameters, and must be multiplied by the appropriate voltage and temperature derating factors for a given application.

Timing Derating Factor (Temperature and Voltage)

	Industrial		Military	
	Min.	Max.	Min.	Max.
(Commercial Specification) x	0.69	1.11	0.67	1.23

Timing Derating Factor for Designs at Typical Temperature ($T_J = 25^\circ\text{C}$) and Voltage (5.0V)

(Maximum Specification, Worst-Case Condition) x	0.85
---	------

Note: *This derating factor applies to all routing and propagation delays.*

Temperature and Voltage Derating Factors

Notes:

- For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDn}$, $t_{CO} + t_{RD1} + t_{PDn}$ or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.
- Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on the device prior to shipment.
- Data applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the DirectTime Analyzer utility.
- Set-up and hold timing parameters for the input buffer latch are defined with respect to the PAD and the D input. External set-up/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal set-up (hold) time.
- $V_{CC} = 3.0\text{V}$ for 3.3V specifications.

f_{MAX}	Flip-Flop (Latch) Clock Frequency		215.0		190.0		160.0		110.0		105.0		120.0	MHz

Notes:

- For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDn}$, $t_{CO} + t_{RD1} + t_{PDn}$ or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.
- Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on the device prior to shipment.
- Data applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the DirectTime Analyzer utility.
- Set-up and hold timing parameters for the input buffer latch are defined with respect to the PAD and the D input. External set-up/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal set-up (hold) time.
- $V_{CC} = 3.0\text{V}$ for 3.3V specifications.

Notes:

1. For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDR}$, $t_{CO} + t_{RD1} + t_{PDR}$, or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.
2. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on the device prior to shipment.
3. Data applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the DirectTime Analyzer utility.
4. Set-up and hold timing parameters for the input buffer latch are defined with respect to the PAD and the D input. External set-up/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal set-up (hold) time.
5. $V_{CC} = 3.0\text{V}$ for 3.3V specifications.

t _{WASYN}	Flip-Flop (Latch) Asynchronous Pulse Width	4.1		5.5		6.5		8.4		7.6		6.5		ns

Notes:

- For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDR}$, $t_{CO} + t_{RD1} + t_{PDR}$, or $t_{PD1} + t_{RD1} + t_{SUD}$ whichever is appropriate.
- Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on the device prior to shipment.
- Data applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the DirectTime Analyzer utility.
- Set-Up and hold timing parameters for the input buffer latch are defined with respect to the PAD and the D input. External set-up/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal set-up (hold) time.

Notes:

1. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance.
2. SSO information can be found in the "Simultaneously Switching Output Limits for Actel FPGAs" application note on page 4-125.

Package Pin Assignments (continued)

240-Pin RQFP Package (Top View)

Notes:

1. *I/O (WD) : Denotes I/O pin with an associated wide-decode module.*
2. *Wide-Decode I/O (WD) can also be general purpose user I/O.*
3. *NC: Denotes 'No Connection.'*
4. *All unlisted pin numbers are user I/O's.*
5. *MODE should be terminated to GND through a 10K resistor to enable ActionProbe usage; otherwise it can be terminated directly to GND.*
6. *RQFP has an exposed circular metal heat sink on the top surface.*
